CTEXT database

Corpus of 96 Classical Chinese texts from the CTEXT database

- \sim 1000 BCE 200 CE
- N tokens

Shangshu of 58 chapters:

Period	Chapters
Pre-Warring	10
Warring	16
Late Warring - Early Han	7
Han	25

Text-age (mis-)classifier

Train a simple and transparent learning model to explore the boundaries of age classification

- compare age-central to age-peripheral chapters of the Shangshu
- "misclassification semantics"

The probability of a document d being in class c, $P(c \mid d)$ is computed as:

$$P(c \mid d) \propto P(c) \prod_{i=1}^{m} P(t_i \mid c)$$

and the class of a document d is computed as:

$$c_{MAP} = arg \ max_{c \in \{c_1, c_2\}} P(c \mid d)$$

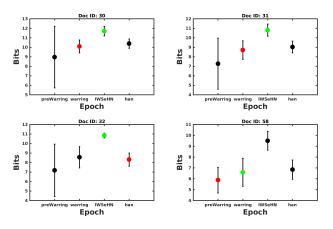

Figure 2: Average distance* to all classes show that the error class is closer to the document than the correct class

The distance between documents $s^{(1)}$ and $s^{(2)}$:

$$D_{KL}(s^{(1)} \mid s^{(2)}) = \sum_{i=1}^{K} s_i^{(1)} \times \log_2 \frac{s_i^{(1)}}{s_i^{(2)}}$$

Dense document representation

– model semantic disruption as "variation on a theme" \Rightarrow use a simple Bayesian model to capture lexical semantics

– model each document as a distribution on lexical topics (e.g., $P_1 = [0\ .09\ .78\ .11\ .2]$), where each 'topic' is a distribution on words, and compare document similarity as the distance between any two documents with <code>chapter - index j</code> and <code>k</code>

$$D_{\mathit{KL}}(s^{(j)} \mid s^{(k)}) = \sum_{i=1}^{K} s_i^{(j)} \times \log_2 \frac{s_i^{(j)}}{s_i^{(k)}}$$

– bracket concrete semantics (\sim reduce interpretive load) and only compare relative entropy between documents on topics ("variation on a theme")

Novelty & resonand

Disruptive dynamics

Compute disruption as a combination of resonance on novelty:

Novelty over window w:

$$\mathbb{N}_{w}(j) = \frac{1}{w} \sum_{d=1}^{w} D_{KL}(s^{(j)} \mid s^{(j-d)})$$

with Transience:

$$\mathbb{T}_{w}(j) = \frac{1}{w} \sum_{d=1}^{w} D_{KL}(s^{(j)} \mid s^{(j+d)})$$

for Resonance

$$\mathbb{R}_w(j) = \mathbb{N}_w(j) - \mathbb{T}_w(j)$$
